I. Problem Statement

People frequently require local services such as electricians, plumbers, cleaners, and technicians, but finding reliable service providers, comparing options, and managing bookings is often unorganized and inefficient. Most interactions happen through phone calls or informal messaging, leading to poor tracking of service history, payments, and customer feedback. Service providers also lack a structured system to manage availability and requests.

There is a need for a centralized database-driven system that can store and manage service provider information, customer bookings, and transaction records in an organized manner.

II. Objective

- To design a relational database system for managing local service providers and customer bookings.
- To store structured data related to users, services, schedules, and transactions.
- To support booking, scheduling, and status tracking of services.
- To maintain payment records and customer feedback.
- To enable efficient querying and retrieval of service and booking data.

III. Methodology

Data Design:
Identify entities such as Users, Service Providers, Service Categories, Bookings, Payments, and Reviews, and define relationships among them..

Database Implementation:
Create tables using SQL with primary and foreign key constraints to ensure data integrity.

Query Implementation:
Develop basic and complex SQL queries for operations such as searching services, viewing booking history, and analyzing provider performance.

Testing:
Validate data consistency, relationships, and correctness of queries.
